RLE-593

This Krack Manual was published for the purpose of providing a concise, complete and convenient load estimating reference volume for the commercial refrigeration industry. Application suggestions and unit cooler selection examples are representative for halocarbon direct expansion fed systems.

Load estimating data can be used for industrial refrigeration systems using ammonia or brine as the refrigerant.

Estimating guidelines and rules of thumb, are necessarily general in nature, and should not be utilized as the sole design criteria.

Product freezing and cooling data was developed in the Krack product testing laboratory. Other data has been extracted by permission from various ASHRAE Guide and Data Book publications.

PRINCIPLES OF HEAT TRANSMISSION

PRELIMINARY CONSIDERATIONS

Calculation of the heat transfer through the walls, floor and ceiling of a refrigerated space requires determination of the overall coefficient of heat transmission (or 'U' value, as it is commonly called) for the building structure.

Accordingly, the procedures utilized to determine this coefficient, and the several factors which affect its value, are briefly discussed below.

It is to be noted that rapidly increasing energy costs have made obvious the desirability of optimum insulation efficiency. First-versus-operating cost comparisons are therefore worthwhile, and will often justify an increase in the indicated insulation thickness.

Letter symbols utilized herein are those most commonly employed to designate the various heat transfer factors.

THERMAL CONDUCTIVITY (K)

Thermal conductivity is defined as the rate of heat transfer through a homogeneous material in Btu per hour per square foot of area per °F temperature differential per inch of thickness (NOTE: A homogeneous material is one whose thermal conductivity is essentially unaffected by a change in surface area or thickness).

Conduction heat transfer varies directly with thermal conductivity, surface area, temperature differential and time, and varies inversely with material thickness. Accordingly, the heat transfer into a refrigerated space may be reduced either by selecting an insulating medium with a lower K value, or by increasing the insulation thickness.

The daily heat transfer through any homogeneous material of a given thickness may be calculated by utilizing the following formula:

$$Q \text{ Btu / 24 hrs} = \frac{K \times \text{Area sq ft} \times TD_{\circ F} \times 24}{\text{Thickness in}}$$

K always expresses a heat transfer value per inch of thickness in air conditioning and refrigeration considerations.

CONDUCTANCE (C)

Thermal conductance (C) differs from thermal conductivity (K) only in that it is a heat transfer factor for a specific building material having a standard thickness. All non-homogeneous materials are necessarily rated in this manner (as opposed to K), examples being tile & concrete block, Building boards and paper, flooring materials, air spaces and various materials common in general construction are also rated by C values.

Thermal conductance is by definition, therefore, the rate of heat transfer through a specific material in Btu per hour per square foot of area per °F temperature differential.

Conductances for various material categories are tabulated in Table 1B in the Appendix.

It is to be noted that the formula listed above for calculating heat transfer through various thicknesses of homogeneous substances would not apply for materials rated by conductance.

SURFACE FILM CONDUCTANCE (f)

The surface of any material offers an additional resistance to heat flow, with the absolute value being dependent upon its reflectivity, degree of roughness, attitude (vertical or horizontal), length and the air velocity over the surface.

The reciprocal of this resistance is the surface film conductance (f) which is expressed in the same units as conductance (ie, Btu per hour per square foot of area per °F temperature differential.)

Inside surface film conductance is designated by f_i , and may usually be estimated at 1.60 for walls in still air not exposed to outdoor conditions.

Outside surface film conductance is designated by f_o , and may be approximated at 6.0 for outdoor walls not exposed to winds in excess of 15 MPH.

PRINCIPLES OF HEAT TRANSMISSION

THERMAL RESISTANCE (R)

Thermal resistance is the resistance of a material to heat flow and is, by definition, the reciprocal of a given heat transfer coefficient (ie, C, f_i, f_o etc.):

$$R = \frac{1}{C}$$

As an example, the conductance (C) of $\frac{1}{2}$ inch plaster board (as obtained from Table 1B) is 2.25 Btu per hour per °F temperature differential per sq. ft. Accordingly, its resistance is:

$$R = \frac{1}{2.25} = 0.449^{\circ}\text{F TD / sq ft / Btu / hr}$$

This means that a temperature differential of 0.449°F would be required to transfer 1 Btu of heat across 1 square foot of $\frac{1}{2}$ inch plasterboard surface in 1 hour.

The practical significance of resistance (R) is that its values are additive thereby enabling the calculation of overall coefficients of heat transfer for compound structures, ie:

$$R_{\text{Total}} = R_1 + R_2 + R_3 \text{ (etc.)}$$

OVERALL COEFFICIENT OF HEAT TRANSFER (U)

The overall coefficient of heat transfer of a given material or compound structure with parallel surfaces is commonly known as the U factor, and is expressed in the same units as conductance (ie, Btu per hour per square foot of area per °F temperature differential). It is most generally applied to compound structures such as roofs or walls.

As stated previously, resistance is the reciprocal of conductance and the individual resistances of a structure are additive. Accordingly, it is necessary to determine the overall resistance to heat transfer, and then its reciprocal, to calculate the U factor.

Overall resistance in a compound structure is:

$$R_{\text{Total}} = \frac{1}{C} + \frac{X_1}{K_1} + \frac{X_2}{K_2} + \frac{1}{f_i} + \frac{1}{f_o}$$

Where,

- C is the conductance (if it applies.)
- X₁, X₂, etc. are material thicknesses.
- K₁, K₂, etc. are conductivities.
- f_i is the inside film conductance.
- f_o is the outside film conductance.

The U factor is then calculated as follows:

$$U = \frac{1}{R_{\text{Total}}}$$

An example is useful in illustrating the above. A representative compound structure with parallel surfaces as depicted in Figure A has been selected for this purpose since it is dealt with frequently in refrigeration applications.

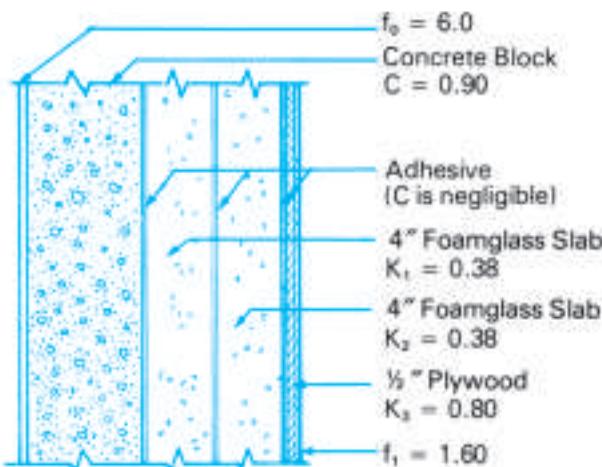

FIGURE A: EXAMPLE CROSS SECTION

In the above example, R_{Total} would equal:

$$R_{\text{Total}} = \frac{1}{0.90} + \frac{4}{0.38} + \frac{4}{0.38} + \frac{0.5}{0.80} + \frac{1}{1.60} + \frac{1}{6.0}$$

or,

$$R_{\text{Total}} = 23.58$$

and,

$$U_{\text{Overall}} = \frac{1}{R_{\text{Total}}} = \frac{1}{23.58} = 0.042$$

JOB SURVEY AND LOAD ESTIMATE

JOB SURVEY

Part II of Krack Survey and Load Estimate Form LE-1 is devoted to the job survey. All factors which affect the rate of heat gain must be detailed. It is suggested that each application be thoroughly reviewed with the operating personnel to determine facility operational characteristics, product pulldown requirements, packaging specifics and such other details as are peculiar to a given application.

Particular attention should be given to the means and frequency of product entrance, adjacent area pressure differentials, existing or required ventilation systems, and related operating characteristics which may produce infiltration loading above the norm (the average air changes detailed in Tables 4A and 4B are intended for standard applications only, and should not be used when specialized conditions prevail).

The product entrance rate, condition and type packaging must be determined to assure an accurate product load estimate. If an individual product is treated as a heat exchanger, the product refrigeration load is then

dependent upon its shape, size and type of packaging, as well as the more usual considerations of entering and leaving temperature differential, product type, entrance rate into the cooler, air temperature and velocity over the product and process duration. A prime purpose of the survey, therefore, is to determine the **rate of product heat evolution** (or rate of heat transfer from the product to the room). Specific examples of various product situations are given in the section devoted to the load estimate.

Part IV of Form LE-1 provides for a sketch of the refrigerated space. All relevant construction features such as column, door and partition locations, ceiling clearances, adjacent area conditions, etc. should be detailed. Supplemental photographs of significant building features are often part of a good survey. Additional survey requirements such as ambient design, room temperature, dimensional data, insulation type & thickness, electrical service and the various miscellaneous loads are self-explanatory.

LOAD ESTIMATE

GENERAL

Part III of Krack Form LE-1 is devoted to calculation of the refrigeration load. Five sources of heat gain must be estimated:

- Wall, floor, & ceiling transmission load
- Solar load
- Infiltration load
- Product load
- Supplemental load

Optimum and efficient equipment selection is dependent upon an accurate determination of each of the above loads.

A brief discussion of each heat gain source follows, with references made where appropriate to factors and data charted in the appendix.

TRANSMISSION LOAD

The heat transmission into a refrigerated space through its ceiling, floor and walls is a function of the outside surface area, the temperature differential between the room and its surrounding area and the thermal conductivity of the insulation utilized.

Table 1A converts thermal conductivity ('K' in Btu / hour / sq. ft / °F temperature differential / inch of thickness) to 24 hour heat gain factors for various thicknesses of commonly used insulation materials at temperature differentials from 1 to 130°F. These factors should be inserted where indicated in Part III, Section A of Form LE-1, and multiplied by surface area to obtain the 24 hour transmission heat gain.

For materials other than those tabulated, or for compound structures, refer to Table 1B for the appropriate thermal conductivities and calculate the overall coefficient of heat transfer (U) as illustrated in the foregoing section. This is then converted to a daily heat gain factor by utilizing the following formula:

LOAD ESTIMATE

$$\text{Heat Gain Factor} = 24 \times U \times TD$$
$$\text{Btu / sq ft / 24 hrs} \quad ^\circ\text{F}$$

It is common practice in calculating heat transmission for low temperature rooms to ignore the resistances of both surface films and the building structure proper since their overall effect is quite nominal.

Heat gain factors for various floor designs are tabulated at the bottom of Table 1A. It is the usual practice to assume a factor of 1 Btu / sq ft / °F / 24 hrs for freezer floors with conventional insulation.

SOLAR LOAD

The heat gain through solar radiation is a function of the exposure, type of surface, latitude, altitude, time of year, time of day and other factors. For load estimating purposes, however, this sun effect can be compensated for by adding the degrees shown in Table 2 to the normal temperature differential as indicated in Section A of the load calculation form.

In instances where the refrigerated facility is on (or adjacent to) a highly reflective surface such as sand or water, the allowances shown in Table 2 should be increased by 50%.

INFILTRATION LOAD

Infiltration into a refrigerated room will occur when a door is opened as a result of the difference in density between the warm and cold air.

Since door openings vary widely, it is the usual practice to estimate infiltration in air changes per 24 hours as shown in Tables 4-A and 4-B. This may then be factored by the room volume and the heat removed in cooling outside air to storage conditions in Btu/cu ft as tabulated in Table 5 to obtain the infiltration load. Space is provided in Part III, Section B of Form LE-1 for computation of this load.

Infiltration may be determined more precisely by calculating the air velocity through the door, the door area and the heat removed in cooling entering air to room conditions, and then estimating the average number of minutes per hour that the door will be open.

The average air velocity in either half of a door 7 feet high at a 60°F temperature differential is 100 feet per minute. Since velocity varies directly with the square root of the doorway height and the square root of the temperature differential across the door, actual air

velocity for any set of conditions may be calculated by utilizing the following formula:

$$\text{Vel fpm} = 100 \times \frac{\sqrt{H}}{\sqrt{7}} \times \frac{\sqrt{TD}}{\sqrt{60}}$$

or,

$$\text{Vel fpm} = 4.88 \times \sqrt{H} \times \sqrt{TD}$$

As an example, the velocity thru a door 8 ft wide and 9 ft high, with a temperature differential of 100°F, is:

$$\text{Vel} = 4.88 \times \sqrt{9} \times \sqrt{100}$$

$$\text{Vel} = 146.4 \text{ fpm}$$

Were the door in this example open 15 min per hour in a 12 hour shift operation, the 24 hour infiltration would be computed as follows:

$$\text{Cu ft} = \text{Vel fpm} \times \frac{\text{Door Area ft}^2}{2} \times \text{Time Open min}$$

or,

$$\text{Cu ft} = 146.4 \times \frac{(8 \times 9)}{2} \times 180 = 948,672$$

This would then be factored by the heat gain per cu ft from Table 5 in the usual way. An alternate approach is to determine the enthalpy difference between room and entering air from the psychrometric chart, and utilize the following formula:

$$\text{Heat Gain Btu / 24 hrs} = 24 \times 4.5^1 \times \text{Cfm} \times \Delta h$$

or,

$$\text{Heat Gain Btu / 24 hrs} = 108 \times \text{Cfm} \times \Delta h$$

In cases where positive ventilation is applied to a space, this load would then replace the infiltration load (if greater).

Note 1: Converts Cfm to lbs/hr (refer to Table 4B, Pg. 47).

LOAD ESTIMATE

PSYCHROMETRICS

The Psychrometric Chart is utilized to determine the infiltration heat gain for specialized conditions, or for temperature changes not tabulated in Table 5.

Charts 2 and 3 at the rear of the Appendix are applicable to normal temperature (32°F to 130°F) and low temperature (-40°F to 50°F) conditions, respectively. Both charts are based on a standard atmospheric (or sea level) pressure of 29.921 in Hg, and must be corrected for other altitudes.

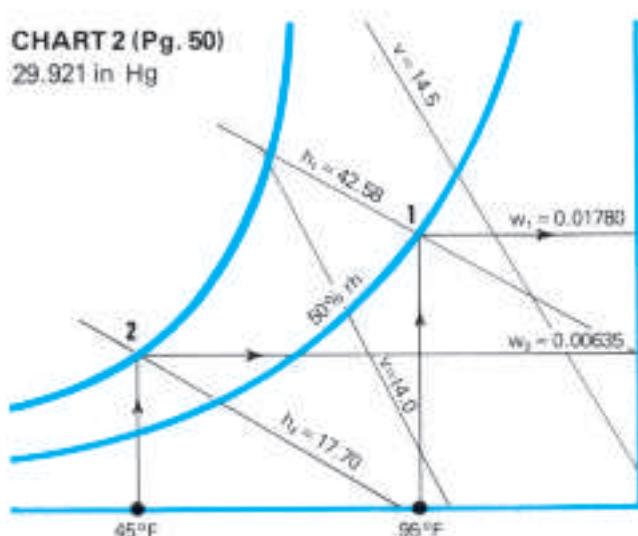

For purposes of approximating infiltration loads at higher altitudes, it may be assumed that:

- Relative humidity (rh) remains constant,
- Enthalpy (h) and humidity ratio (w) increase 2% and 5% respectively per 1000 ft. increase in altitude, and,
- Volume (v) for a given dry bulb and humidity ratio is inversely proportional to atmospheric pressure.

Atmospheric pressures at various altitudes are tabulated at the bottom of Chart 3.

An example is useful in demonstrating the use of the psychrometric chart in the calculation of infiltration heat gain. Assuming an infiltration rate of 500 Cfm, an entering air condition of 95°F dbt & 50%rh and a cooler temperature of 45°F , characteristics of the entering and cooled air are first determined as in Figure B:

CHART 2 (Pg. 50)
29.921 in Hg

SCHEMATIC SOLUTION OF EXAMPLE

As indicated in Figure B, the properties of the entering and cooled air are:

$$\begin{aligned}h_1 &= 42.58 \text{ Btu / lb of dry air} \\w_1 &= 0.01780 \text{ lb H}_2\text{O / lb of dry air} \\v_1 &= 14.25 \text{ Cu ft / lb of dry air} \\h_2 &= 17.70 \text{ Btu / lb of dry air} \\w_2 &= 0.00635 \text{ lb H}_2\text{O / lb of dry air}\end{aligned}$$

Infiltration heat gain may then be calculated as follows:

$$\begin{aligned}\text{Heat Gain Btu / hr} &= 4.5 \times \text{Cfm} \times (h_1 - h_2) \\&\text{or,} \\Q &= 4.5 \times 500 \times (42.58 - 17.70) = 55,980 \text{ Btu / hr}\end{aligned}$$

For an 8 hour shift operation, the 24 hr infiltration heat gain would therefore be 447,840 Btu, and this load would be inserted in the space provided in Part III, Section B of Form LE-1.

The above calculation provides a conservative load estimate since it presupposes that the total heat removed from the entering air is transferred to the evaporated refrigerant. This is not the case in as much as heat leaves the coil box as well via the heat content of the condensate. Accordingly, precise calculation of the refrigeration load in any instance in which entering air is cooled below its dew point would be calculated as follows:

$$Q \text{ Btu / hr} = 4.5 \times \text{Cfm} [(h_1 - h_2) - (w_1 - w_2) h_w]$$

This effect is illustrated by comparing the $1.746 \text{ Btu / cu ft} \left(\frac{42.58 - 17.70}{14.25} \right)$ heat removal indicated with the $1.710 \text{ Btu / cu ft}$ tabulated in Table 5 for comparable conditions.

Additionally, the factor of 4.5 utilized to convert Cfm to lbs / hr incorporates the standard (70°F) dry air conversion factor of 13.33 cu ft / lb . Obviously, therefore, additional safety is built into the sample calculation since utilization of the actual entering volume of 14.25 cu ft/lb would result in a lower mass flow.

It is to be noted that the psychrometric chart is useful in calculating numerous other processes involving the conditioning or mixing of moist air, and that no attempt was made in this manual to fully develop the subject.

LOAD ESTIMATE

PRODUCT LOAD

The heat gain from product loading may consist of one or more of the following:

- Sensible heat removal above freezing
- Latent heat
- Sensible heat removal below freezing
- Heat of respiration

Sensible heat is calculated by factoring the **daily rate** of product in lbs per 24 hours by the temperature reduction and the product specific heat (the specific heat being the number of Btu's required to lower 1 lb. of a substance 1 degree fahrenheit).

Latent heat is calculated by factoring the **daily rate** of product in lbs per 24 hours by the product latent heat of fusion (the latent heat being the number of Btu / lb required to freeze the product).

Applicable formulas are:

$$Q_{\text{Sens}} \text{ Btu / 24 hrs} = \text{Daily Rate} \times \Delta T \times \text{Sp. Ht.}$$

$$Q_{\text{Lat}} \text{ Btu / 24 hrs} = \text{Daily Rate} \times h_L \text{ Btu / lb}$$

Specific heats (above and below freezing) and the latent heats of fusion for commonly encountered products are detailed in Table 9. Product loads may be figured in the space provided under Part III, Section C of Form LE-1.

As stressed in prior comments relating to the job survey, it is imperative that the rate of product heat evolution be accurately determined. Therein is the significance of **daily rate**, since it is, by definition, the amount of product cooled or frozen per hour multiplied by 24 hours. This may be illustrated by considering two freezers, each of which has been loaded with 10,000 lbs of unfrozen product. In the first instance, eviscerated chickens are to be blast frozen in 2 hours, with the resultant **daily rate** being:

$$\text{Daily Rate lbs/24 hrs} = \frac{10,000}{2} \times 24 = 120,000$$

In the second case, the product is packaged, boxed, and palletized, and therefore requires 16 hours to give up its heat. Accordingly, the **daily rate** is:

$$\text{Daily Rate lbs/24 hrs} = \frac{10,000}{16} \times 24 = 15,000$$

PRODUCT CHILLING

Product chilling is a process wherein product temperatures are rapidly reduced to a level acceptable for processing or shipment. Examples are freshly slaughtered carcasses and recently harvested fruits or vegetables. The benefits of rapid temperature reduction, in each instance, are a reduction in shrinkage and the deterrence of bacterial growth.

The introduction of hot product into a chill room results in the concentration of a significant load segment during the initial cooling period. This initial high rate of product heat evolution is caused by the high temperature and vapor pressure differentials between the product and the room. The effect is illustrated in Figure H, Page 29, wherein temperature reduction versus chill time for hogs is graphically depicted.

Load factors (or chill factors as they are sometimes called) have been developed to compensate for the non-uniform distribution of product load which results. These are utilized to increase the average hourly product load which would otherwise apply. Factors for the products most commonly encountered in chilling applications are charted in Table 10, and should be inserted in the space provided in Part III, Section C of Form LE-1 when applicable. The overall refrigeration requirements for beef and pork chilling rooms are charted in Page 28, Tables 11 and 12, respectively.

As an example, laboratory testing has shown that hogs tend to give up their heat during the initial portion of their chill at a 45% greater rate than is average for the complete period. Accordingly, the load factor indicated is 1.45.

LOAD ESTIMATE

PRODUCT CHILLING (CON'T.)

Failure to apply a load factor to the average hourly load (when applicable) will result in an unacceptably high initial room temperature, and an extension of the chill time required.

The substantial reduction in product load during the latter portion of the chill (15-25% of peak load) makes it mandatory that the refrigeration system be designed for proper function under a wide variance in load condition. Properly staged capacity reduction, in conjunction with evaporator pressure regulating valves, is commonly employed. Other approaches include the application of multi-circuit DX coils, and the combining of other (and more constant) side loads with the basic chill room load to enable high side equipment to stay on line and track the chill load as it tails off.

Suction accumulators and liquid-suction heat exchangers are strongly recommended with close coupled DX halocarbon systems.

PRODUCT CHILLING & HOLDING

Frequently, the same room is utilized to accommodate both the product chilling and long term storage requirements. This is particularly true in the case of apples and pears.

In such rooms, the peak load varies with the duration of the loading period and the maximum percentage loaded on any given day. Normally, however, it is **neither necessary nor advisable** to apply a load factor to the average hourly load since an unacceptable disparity between the peak and holding requirements will result (see Note 5, Table 10).

A common load estimating technique for combined fruit chilling and storage applications is to add the 24-hour pulldown requirement for the last day's loading to the normal room holding load (the apple storage loads charted in Table 16 were computed on this basis).

A prime consideration in this regard is that the on-hand pre-chilled product produces a flywheel effect which minimizes the increase in room temperature which would otherwise result.

Combined chilling and holding facilities may require that existing prechilled product be segregated (either by physical partition or zoned air distribution) from the newly introduced hot product. Otherwise, the significant increase in room relative humidity which results upon the introduction of hot product will produce condensation on the prechilled product. Meat, for example, will sweat and slime, and the bacterial growth rate will be greatly enhanced (meat processed under such conditions would not meet with USDA acceptance).

As is the case with rooms applied for product chilling only, particular attention must be given in the refrigeration plant design to the wide disparity between the peak and normal holding loads. In a fruit storage facility, for example, the winter holding load will approximate 10 to 15% of the peak refrigeration requirement, and the coil TD under holding conditions may, therefore, be only 2-3°F (versus the 15°F and higher TD's experienced under peak pulldown conditions).

Accordingly, flooded or recirculated refrigerant systems are the most frequently utilized since they adapt well to the wide control variance required. When a DX halocarbon system is applied, the comments detailed above under "Product Chilling" apply. Unit coolers with multi-speed fans are sometimes utilized, but should be applied with discretion given the necessity for positive air circulation through the load during storage.

As a final consideration, the refrigeration design engineer should remember that his responsibility is confined to the creation and maintenance of a specific room environment. It is neither his function or purpose, nor is it within his capability, to guarantee a given product core temperature within a specified time frame given the many variables (product condition, packaging, wrapping, entrance rate, means of storage, etc.).

LOAD ESTIMATE

PRODUCT BLAST FREEZING

Air blast freezing offers an alternative to the conventional contact method wherein the product is placed in direct contact with pipes or plates thru which refrigerant or brine is piped.

Batch freezing is a process wherein the complete product load is placed in the room and frozen in one loading. The resultant load profile approximates that previously described for chill rooms in that a major portion of the load is concentrated during the initial freezing period¹. Accordingly, a factor of 1.5 is applied to the average hourly load, and the Daily Rate on Form LE-1 is computed by:

$$\text{Daily Rate} = \frac{\text{Product Load lbs}}{\text{Freezing Period hrs}} \times 24 \times 1.5$$

The 1.5 factor is not to be used when products are frozen over an extended period (these usually being products which are packaged or otherwise not susceptible to significant moisture loss during freezing).

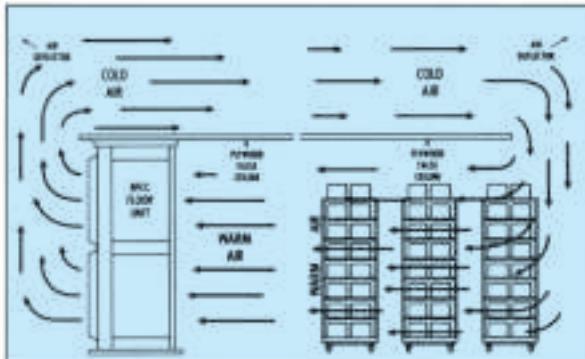

FIGURE C: BATCH FREEZING (FLOOR MOUNT)

Continuous load freezing is a process wherein the product is fed continuously thru the freezer via a conveyor or systemized manual feed. In this type of application, the estimated time of product heat removal has little effect on the total refrigeration load (it does, however, affect room size, conveyor belt size and speed, etc.).

Accordingly, no load factor is applicable and the Daily Rate is computed by:

$$\text{Daily Rate} = \frac{\text{Product Load lbs}}{\text{Process Duration hrs}} \times 24$$

Air temperature, air velocity, product loading technique, and space requirements are critical considerations in the design of blast freezing systems (it seems that adequate space for both the equipment and product is never available). Additional comments, and general guidelines, are detailed in the preamble to Example II, Pg. 14.

Figures C, D & E depict typical room layouts for batch and conveyor-fed blast freezers.

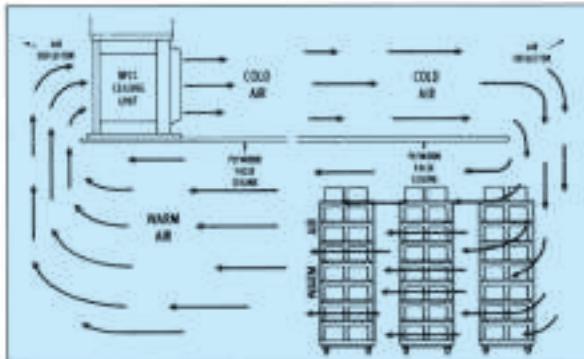

FIGURE D: BATCH FREEZING (CEILING MOUNT)

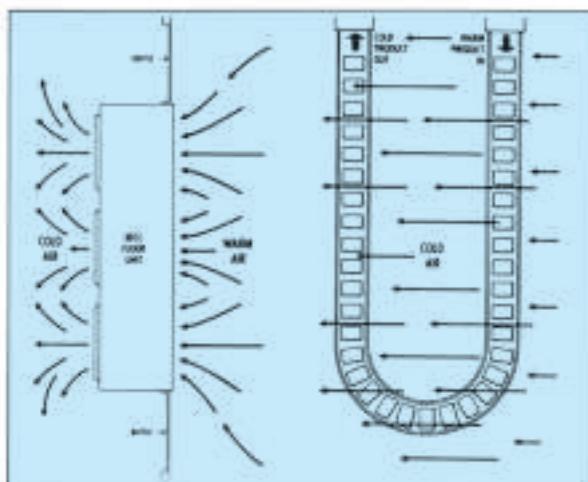

FIGURE E: PROCESS BLAST FREEZING

Note 1: As a product freezes, its outer frozen portion becomes an insulator and its rate of heat evolution decreases accordingly.

LOAD ESTIMATE

RESPIRATION

Fruits and vegetables are living organisms which continue to respire and carry on certain other life processes after harvesting. The carbon in the product combines with the oxygen in the air with the resulting chemical process being exothermic. This, in turn, results in an additional room heat gain.

The heats of respiration for various products in Btu/lb/24 hrs are tabulated in Table 9 at the temperatures recommended for both long and short term storage. Respiration heat (or reaction heat as it is sometimes called) varies with temperature, and decreases significantly with a reduction in storage temperature. There is no correlation, however, between respiration and relative humidity.

Since living organisms are involved, the temperature in long term storage rooms should be controlled within 1°F; otherwise, the physiology of the product will be affected, and the dormant state in which it has been maintained will be disturbed.

Meats and fish have no continuing life process, and therefore generate no heat in storage.

The respiration heat in controlled atmosphere (CA) storage will be less than the values charted in Table 9 as a result of the reduction in room oxygen content.

SUPPLEMENTAL LOAD

All additional heat dissipated in the refrigerated space must be accounted for in computing the overall load. This includes energy utilized for motors, heaters, lights, people, forklifts and related miscellaneous heat sources. Supplemental loads of this type are computed in Part III, Section D of Form LE-1.

Occupancy loads are tabulated in Table 6. The heat equivalents noted should be increased by 20% if occupancy periods are of short duration. Utilize the average number of personnel in the space.

Heat equivalents for **electric motors** are listed in Table 3 for each possible application (ie, motor and connected load in the refrigerated space, connected load only in the refrigerated space and motor only in the refrigerated space). Equivalent horsepower is determined by multiplying the motor horsepower by the fraction of each hour operated.

Storage room lighting may usually be assumed at 1 to 1½ watts/sq ft. Doors, offices and work rooms require 2½ to 3 watts / sq ft. Forklifts may be estimated at 4 to 5 hp if more precise data is unavailable, and should be converted to equivalent horsepower as above.

The **defrost heat load** in a refrigerated space varies with the rate and time which heat is required, and, in some cases, with the unit cooler design¹. In section D of

Form LE-1, 25% of the heat imposed is arbitrarily allocated to room load (the assumption being that this amount is either radiated to the room or retained by the coil mass, with the remainder leaving via the coil condensate).

Charts, trays, racks, pallets, etc. seldom contribute a significant load, but must be accounted for in high volume operations.

Electric energy from any source may be estimated by multiplying the applicable wattage by 82 (24 hrs × 3.4 Btu / Watt / hr).

HOURLY LOAD CONVERSION

The 24 hour total obtained by adding Sections A thru D of Part III, Form LE-1 is converted to design refrigeration load in Btu/hr by applying time cycle and safety factors.

Time cycle factors for various applications are charted in Table 8. The divisors listed in column 1 represent anticipated operating hours under various frost conditions. The operating times noted are **average**, and are not applicable to all applications. Some freezers, for example, may require defrosting only once daily (or, in extreme cases, once weekly). The factor selected, therefore, represents a judgment consideration based upon the amount of moisture expected to enter the space from infiltration, product shrinkage, etc.

A **safety factor** correction of 5 to 10% to the hourly load resulting above is suggested. The figure selected is, again, a judgment consideration. Factors in excess of 10% should not be necessary.

OTHER CONSIDERATIONS

Data herein, and the overall format of Form LE-1, both presuppose a "total load" estimating approach (ie, the combining of sensible and latent loads). Accordingly, evaporative loads such as those resulting from product moisture loss, wash water, etc. have not been considered since they have no net effect on the total room load (the resultant latent heat gains serve as credits to the sensible heat load due to the evaporative cooling effect).

This approach satisfies the requirements of most applications. This is particularly the case with freezers at 15°F or below since variation of the Apparatus Dew Point (ie, the average coil surface temperature) has little or no effect on the sensible heat factor, or the moisture removal capability of the coil.

Further, adherence to the guidelines charted in Tables 17 and 18 for recommended coil TD will produce required room relative humidities in most instances. In those cases where long storage under close humidity control is indicated, however, the possible requirement for reheat or re-humidification must be investigated.

APPLICATION EXAMPLE

I. FRUIT CHILLING AND STORAGE:

The example below illustrates the load profile for a typical combination chilling/holding facility. Three common product load estimating techniques are shown, with the pre-calculated values charted in Table 16 offering the simplest approach (note that respiration heat is neglected when a load factor is applied to the average hourly pulldown load).

Room design dry bulb varies with product variety. The control temperature for apples, as an example, ranges from 38°F for McIntosh (as shown) to 32°F for Golden Delicious. Relative humidity is maintained at 85% for apples, and 92-95% for pears. Room condition is not significantly affected by daily product loading due to the flywheel effect of the on-hand pre-chilled fruit. (Note that **room temperature only** should be guaranteed, and that no commitment as to time required for product pulldown should be made due to the many uncontrollable factors. [ie, type of packaging, position in the load, method of stacking, etc.].

Fruit stored for extended periods (over 3 months) is usually maintained under controlled atmosphere (or C.A.) storage conditions wherein the O₂ concentration is reduced from the normal 20% to a level of 3-7%, with a corresponding increase in the CO₂ level from a trace to 2-5% (the purpose of C.A. storage being to minimize product deterioration during storage). Respiration heat is reduced to a fraction of the normal rate as a result of the low O₂ concentration. C.A. storage facilities are commonly sub-divided into 50' x 100' x 20'

modules to enable product availability in saleable quantities when the room seals are broken. Water defrost and 460V TENV motors are frequently utilized to maximize reliability, and control devices are externally mounted for serviceability given the non-accessible environment.

Apples are usually containerized in lug or wood boxes, or in fiber cartons. The fruit may be individually tissue wrapped, or placed in poly-bags. Ungraded fruit is stored in 1000 lb 2½' x 4' x 4' tote bins. Product loading density averages 25 lb/cu ft.

The refrigeration system for a combination chilling/holding facility must be specifically designed for adequate function under the widely divergent pulldown and winter holding loads. Since operational coil TD's will range from 15°F (or higher) during pulldown to 2°F (or less) with the winter holding load, flooded or recirculated systems are the most readily adapted to fruit storage applications.

When a DX system is applied, it must incorporate properly staged capacity reduction in consideration of the wide load variance. Multi-speed fan motors may also be applied, but have an obvious adverse effect on air movement thru the load.

Coils should be selected for a 6-8°F TD to maintain required humidity. Since all rooms require defrosting, a 4 FPI coil design is recommended.

Refer to the text, Pg. 10, for more detailed information.

APPLICATION EXAMPLE

II. BLAST FREEZING:

As illustrated in the example, the load profile of a batch blast freezing process dictates the application of a load factor to the average hourly load which would otherwise apply. The result is a refrigeration system properly adapted to the initial high rate of product heat evolution. The usual factor is 1.5, but a lower number is sometimes applied based on experience. In general, products with high surface-to-weight ratios freeze in 2 to 4 hours, and lower factors are therefore applicable when an extended freezing period is allowed. Note that no load factor should be applied to conveyor fed blast freezers, or to rooms equipped with single halocarbon refrigeration systems (in the latter, freezing time should be extended, and the room temperature allowed to rise).

Special design considerations include the provision for room pressure relief, and the consistent problem of obtaining adequate space to accommodate both the equipment and product. Provision for heater pull space must be made with electric defrost units. Utilization of coils with variable fin spacing minimizes the defrost requirement.

The following procedure should be followed in arriving at a blast freezer design:

STEP 1: Determine whether a conveyor or batch loaded freezer is best applied. This judgment is usually based on product test data wherein freezing time with various air temperatures and velocities has been determined. In general, batch loaded freezing is applied with products requiring 1%

hours or more to freeze satisfactorily; products which freeze in less than 1 $\frac{1}{2}$ hours are conveyor fed.

STEP 2: Determine the space limitations of the room (remember that the space initially allocated by others is frequently insufficient to accommodate both the equipment and the product).

STEP 3: Finalize the room design criteria, keeping in mind that design air velocity and temperature are most critical, and that these factors are the prime considerations in the selection of a blast freezing unit.

STEP 4: Select equipment as dictated by room size and product mass, and which is in conformance with the required air temperature and velocity as finalized in Step 3 (following review of the pilot freezing test results). The equipment employed should be specifically designed for blast freezing application, and should be capable of producing extremely high air velocities and volumes.

STEP 5: The last step is to position the unit in the room. Refer to Figures C & D, Pg. 11, for typical batch loaded blast freezers. Note that the air travels from right to left in these diagrams, passing thru the product and gradually warming up before being returned to the coil. A critical requirement in blast freezing of this type is that product be loaded across the complete room width thereby precluding the cold air bypass which would otherwise destroy the effectiveness of the freezer.

Refer to the text, Pg 10, for further discussion, and to Table 13, pg. 28, for test blast freezing data on selected products.

APPLICATION EXAMPLE

III. BEEF CARCASS CHILLING:

The load characteristics of a carcass chill room for the "Hot" cooler, as it is commonly called! are such that the application of a load factor to the average hourly product load is mandatory. The initial rate of heat evolution has been shown by test to exceed the average hourly rate by 50%. Hence the load factor applicable is 1.50. The typical load profile is illustrated in figure H, Page 29, wherein time/temperature curves for Hot Chilling are plotted.

Other specialized design and operational requirements apply. Rail height as dictated by USDA must be 11'2", and a 4 to 5 ft clearance above the rails is required for supporting structure and equipment placement; accordingly ceiling height should be 16 ft at a minimum. BTR units are specifically designed for this application, and should be utilized whenever possible (these units will accommodate 2 rails on either side).

Small plants can present particular problems. Frequently, 12 or 14 ft ceiling heights are encountered, as is the placement of structural steel within the envelope. In an application of this type, it is essential that the refrigeration be coordinated with the structure to assure a clear air flow at the discharge of the unit coolers. Hite-saver® or draw-thru type unit coolers must be flush-mounted with the ceiling around the periphery of the room.

An additional USDA requirement is that drain pans be insulated to prevent drippage on the product; stainless

enclosures as found on the BTR series are optimum.

Unit coolers should be of 4 FPI coil construction, and be selected for a 10-12°F TD (the initial TD will approach 18-20°F, but will drop rapidly with the fall-off in load). Variable fin spacing (wherein the first 2 rows are of 2 FPI construction) minimizes the defrost requirement, but is not recommended for DXF applications since a 2 fin per inch coil face produces marginal superheat.

Defrost is usually accomplished 4 times daily, with each cycle being of 15 to 20 min duration. Small rooms usually approximate 40 sq ft / ton, with large facilities approaching 65-70 sq ft / ton. The following guidelines may be applied:

- * 5 head per ton
 - * 8 sq ft per head

The refrigeration plant should be designed to adapt to the wide load variance. Multiple compressors with unloaders are recommended (a twin unit is illustrated in the example). Improperly applied equipment will short cycle, pump-down the coils, and thereby dry out the product.

As a final consideration, it should be noted that round temperature cannot be pulled down in 18-24 hours. Accordingly, a product load must be estimated for the holding cooler which will approximate a 15 degree, 24 hour pull-down of 10% of the carcass weight (utilize 20% of the overall weight for small rooms).

Refer to USDA handbook 191 for detailed meat packing-plant design guidelines, and to tables 11 & 12, Pg. 28, for pre-calculated chill room loads.

FORM LE-1

PART II - SURVEY DATA

PART III – LOAD CALCULATIONS:

APPLICATION EXAMPLE

IV. BEER STORAGE:

Beer storage facilities are refrigerated for the purpose of maintaining product quality with an extended shelf life (from the usual 90 days, to as much as 180 days at 40°F). The expense is justified by the cyclical nature of industry sales. Storage temperatures vary from 40°F to 76°F, with the control point being adjusted in accordance with the dew point profile of a given area (the reason being that cartoning would otherwise disintegrate upon exposure to ambient conditions). Draught beer (kegs) is stored in a separate cooler since it must be maintained at a constant temperature year-round (the range being from 34°F to 38°F).

The product leaves the brewery's pasteurizer at a maximum temperature of 85°F, with its temperature range prior to arrival at the distribution point increasing (decreasing) 1°F per day if shipment is by truck, or 1°F per day if shipment is by rail.

Beer is shipped by pallet, with a rail car containing 50 pallets. Car loadings are mixed in accordance with a distributor's sales profile. Kegs may be included with a can or bottle load behind a bulkhead packed with dry ice. Pallets are wood, and vary in weight with location from 36 to 44 lbs. (for cans), to 55 lbs. (for kegs); 42 lbs. is the most common weight encountered with cans or bottles. Dimensions are 32" x 37" x 73".

Pallet refrigeration loads based on a 45°F/24 hour product pulldown are as follows:

TYPE CONTAINER	CASES/ PALLET	BTU/45°F/ 24 HR
• 12 oz tray steel can	98	85,000
• 12 oz tray alum. can	98	84,800

C. SUPPLEMENTAL DATA:		
① CONTROL PT VARIABLE BETWEEN 40/72°F.		
② INVENTORY IS 85% CANES - ALL STEEL EXCEPT "LIGHT" BEERS.		

The following procedure should be followed in estimating the refrigeration load:

STEP 1: Determine facility operational specifics such as method of truck loading (end or side), the percent of pre-sold/scheduled deliveries vs. driver sales, the required number of pallet facings, a 5 year sales projection, the average number of inbound car loads/day, etc.

STEP 2: Following review of the above with operating personnel, define the space to be refrigerated (the primary concern being whether the loading and staging areas should be refrigerated). It is the usual practice to size for expansion planned over a 5 year period.

STEP 3: Determine the distributor's annual sales profile by product category, and compute the average pallet refrigeration load on a weighted average basis.

STEP 4: Obtain the area dew point profile, and subsequently establish minimum storage temperature by month.

STEP 5: Estimate the heat gain for each of several representative months to determine the peak load. (NOTE: As illustrated in the example, the peak load will occasionally occur during a winter month due to maximum product pulldown requirements).

STEP 6: Review alternate insulation options to those assumed in Step 5 above. A compound U value of .080 is a commonly accepted design, but values as low as .035 are sometimes justified.

STEP 7: Design the refrigeration system for proper function under the load variance determined in Step 5 above. Coil TD is not critical; utilize 6 FPI construction.

See Tables 29 thru 32, Page 37, for additional product load and container data.

APPLICATION EXAMPLE

V. NUT STORAGE:

Nuts are received from growers during the October thru February harvest season packed in burlap bags. Bag weights vary from 90 lb (for high quality) to 150 lb (for small size, or seedlings); average bag weight is 125 lb, with a truck load being 360 to 400 bags.

Upon receipt at the processing and storage facility, the product is cleaned, sized, and graded, with miscellaneous shells, trash, etc. being removed. It is then segregated into 7 or 8 categories by size, and packed loose in 60" x 42" x 42" wood tote boxes for transfer to storage. Box weights average 170 lbs, with each containing 1800 to 2000 lbs of product. Entrance rate into the cooler is a function of the grading machinery capacity (and not the rate of inbound shipments from growers).

Tote boxes are generally stacked 4 high (or 20 ft). The box bottoms and sides are perforated with small holes, and these, in combination with the loosely packed nature of the product, enable adequate air movement thru the load.

Customer orders are filled from storage, with the appropriate size and grade nuts being transferred to the plant area where shelling, cutting and repackaging for customer shipment occur.

Proper storage room design is 28°F to 32°F with a 65% relative humidity; maintenance of constant humidity is critical. Processing and plant areas are not usually air conditioned.

tioned. Since the product enters storage during the fall and winter months, the peak pulldown, transmission and infiltration loads are not coincident (note that incoming product during the summer months usually represents inter-warehouse transfer, and is pre-refrigerated).

The usual practice, therefore, is to estimate the load on the basis of the maximum transmission, infiltration and miscellaneous loads only, with the product load neglected. An alternate load estimating technique is to compute the product load based on 24 hr pulldown at the maximum entrance rate, and add the usual transmission, infiltration and miscellaneous loads recomputed for a lower design ambient (were the example refigured on this basis with a 75°F outdoor design, the net effect would be to reduce the transmission and infiltration loads to 1.8 million and 1.6 million Btu/24 hrs, respectively, with the overall load becoming slightly overstated at 60 tons).

Coils should be selected for a 12°F TD, and may be of 4 or 6 FPI construction. Multiple compressors are recommended to adapt to the widely divergent peak and holding loads.

Provision for reheat is usually necessary to assure maintenance of constant humidity under light load conditions. The simplest approach is to de-energize one refrigeration system while continually operating all unit fans, lights, and a predetermined number of defrost heaters (the net effect being to false load the operative refrigeration unit). This approach requires the addition of a humidistat and humidity relay (the function of the latter being to de-energize the required refrigeration circuitry and to activate the defrost heaters).

APPLICATION EXAMPLE

VI. DISTRIBUTION CENTERS:

The refrigeration load in a food distribution facility differs substantially from that common to holding rooms utilized for the extended (or, long term) storage of seasonal and process foods. Product movement, and the activity level in general, is high, with the result being significantly increased infiltration and supplemental heat gains.

The produce cooler depicted in the example is illustrative of the application in general. Rooms of this type are maintained at 32-35°F with high humidity, and open into a staging or loading area most frequently controlled at 50-55°F. There is a significant infiltration heat gain resulting from the high frequency of product movement (it is not uncommon for the entrance doors to be open 50% or more of the time). Vestibule and air doors, or strip curtains, appreciably reduce this load, but are often not employed. Consequently, the infiltration load can approach 2 to 2.5 tons per door. An additional characteristic of this type room is the significant product load resulting from reaction heat; this load may usually be estimated at .003 to .004 tons/sq ft, and the room load overall will generally fall between 150 and 200 sq ft/ton. Proper equipment application dictates unit coolers selected for a 6-9°F coil T.D., with face velocities not in excess of 600 FPM for wet coil operation, or 700 FPM for light frosted operation. The over-riding design consideration in these rooms is the prevention of product damage from shrinkage, drying, or mold growth.

Deli coolers are generally maintained at a slightly lower temperature (30-33°F), and represent an even more severe

application from the standpoint of infiltration. In many rooms, the doors are never closed, with the resulting infiltration gain being 3.5 to 4 tons/door. The overall room load usually approximates 200 to 225 sq ft/ton.

The load in holding freezers is dependent in large measure on the condition of the inbound product. Frequently, a 10 to 15°F pulldown load is imposed, and, since movement is heavy, this load is significant. Infiltration can be estimated at 2 tons/door. A load estimating guideline of 200 to 300 sq ft/ton applies due to the wide variance in product load.

The refrigeration requirements for loading docks are difficult to estimate. The activity level is high (personnel, forklifts, etc.), as is the rate of infiltration. Dock seals may be either worn or damaged, or not adaptable to certain trailer cavities. Forced ventilation is sometimes utilized to evacuate exhaust fumes, and, when present, will supplant the usual infiltration load (if greater). Docks are maintained at 35 to 55°F, with the lower temperatures affording the dual advantage of increased flexibility and decreased load imposition on adjacent rooms. Unit coolers should have face velocities under 650 FPM, and be placed such that they blow toward and above the doors to create an air curtain effect. The load range is 150 to 175 sq ft/ton.

Ripening rooms are usually located at the rear of the loading area, and may be of $\frac{1}{2}$, 1 or 2 car capacity. The load range is 3 to 12 tons per room, and is accommodated most effectively with individual halocarbon systems specifically designed for this application. Since the full complement of rooms are seldom (if ever) in simultaneous service, a load diversity factor of .75 can be applied if a central refrigeration plant is utilized.

VII. WALK-IN COOLERS:

GENERAL

Pre-fabricated walk-in coolers and freezers are utilized for a wide variety of refrigerated storage, chilling and freezing applications, the most common of which is the point-of-sale holding room.

Since standard configurations with an extensive experience factor are involved, loads may be precalculated and charted as a matter of convenience.

A brief description of the precalculated walk-in cooler data included herein is as follows:

TABLE NO. **DESCRIPTION**

- 40 Tabulates transmission, infiltration, lighting, occupancy and related miscellaneous loads for 8' and 10' prefabricated coolers in the 40 most common configurations. Note that product load is excluded for the purpose of enabling greater applicational flexibility. Loads are based on:
 - 95°F ambient design
 - Average usage
 - Indoor installation
 - 3" urethane (or equivalent) insulation
 - 18 hour compressor operation
 Correction factors are noted for other ambients, and for light or heavy usage situations.
- 41 Tabulates average product loads by room volume. Data is based on actual Hussmann experience with field applications, and is intended for use with holding rooms only when the specific product loading is unknown.
- 42 Tabulates specific product loads on the basis of 24 hour pulldown with 18 hour operation. This table should be used for all pulldown coolers and freezers, or when the specific product entering rate and condition is known. Note: batch blast freezing, and certain other specialized applications such as ice cream hardening, require adjustment of the 24 hr pulldown data. The applicable formula is:

$$Q_{\text{Btu} / 24 \text{ hrs}} = \frac{\text{Charted Value} \times 24}{\text{Pulldown or Freezing Time hrs}}$$

- 43 Tabulates additional infiltration loads for glass display doors.

Additionally, Table 32 tabulates the total capacity requirements for walk-in beer storage coolers.

Product loads not tabulated in Table 42, or loads for specialized applications, may be estimated in the usual manner utilizing Form LE-1.

SPECIFIC EXAMPLES:

I. Cooler — Average Product Load:

- 10'W x 12'L x 8'H @ 36°F
- 95°F ambient design
- Refrig. load less product (Table 40) 7,000 Btu/hr
- Average product load (Table 41) 1,800 Btu/hr
- Total refriger. load 8,800 Btu/hr

II. Milk Cooler — Specific Product Load:

- 10'W x 12'L x 8'H @ 35°F
- 300 gal/day entering @ 45°F
- 10 hour pulldown
- 80°F ambient design (air cond. space)
- (3) 30" x 66" glass display doors
- Refrig. load less product (Table 40) 7,125 x 0.75 I.C.F. @ 80°F 5,444 Btu/hr
- Product load (Table 42) 456 Btu/hr / 100 gal x $\frac{300}{100} \times \frac{24}{10}$ 3,283 Btu/hr
- Display door infiltration (Table 43) 960 x 3 2,880 Btu/hr
- Total refriger. load 11,607 Btu/hr

III. Holding/Pulldown Freezer:

- 16'W x 32'L x 10'H @ -20°F
- 2000 lbs. fish/day entering @ 35°F
- 100°F ambient design
- Product packaged & boxed
- 16 hour pulldown
- Refrig. load less product (Table 40) 26,600 Btu/hr x 1.10 (C.F. @ 100°F) 29,260 Btu/hr
- Product load (Table 42) 817 Btu/hr / 100 lbs x $\frac{2000}{100} \times \frac{24}{16}$ 24,510 Btu/hr
- Total refriger. load 53,770 Btu/hr

IV. Ice Cream Hardening/Storage Freezer:

- 30'W x 30'L x 10'H @ -20°F
- Soft mix @ 28°F
- Assume maximum daily capacity
- 100% overrun; wgt/gal = 4.6 lbs
- 95°F ambient design
- Refrig. load less product (Table 40) 37,000 Btu/hr
- Product load (Table 42) Assuming 3.3 gal/sq ft (see Table 7, Note 7), the no. of gal to be hardened is: 900 sq ft x 3.3 gal/sq ft = 2970 gal, and the product load based on a 10 hr hardening time is therefore: 3284 Btu/hr / 100 gal x 2970 / 100 x 24 / 10 234,083 Btu/hr
- Total refriger. load 271,083 Btu/hr

V. Beer Cooler:

- 12'W x 20'L x 10'H @ 35°F
- 900 case capacity with 20% daily turn
- Product entering temp. of 50°F
- 95°F ambient design
- Refrig. load less product assuming heavy usage (Table 40) 11,100 x 1.15 (C.F. @ heavy usage) 12,765 Btu/hr
- Product load (Table 42) 2670 Btu/hr / 100 Cases x $\frac{900}{5 \times 100}$ 4,806 Btu/hr
- Total refriger. load 17,571 Btu/hr

APPENDIX—TABLES

TABLE 2 SOLAR RADIATION ALLOWANCE

SURFACE TYPE		'F TO BE ADDED TO NORMAL T.D. (NOTE 1)			
		East Wall	South Wall	West Wall	Flat Roof
DARK	Slate Roofing Tar Roofing Black Paints	8	5	8	20
MEDIUM	Unpainted Wood Brick Red Tile Dark Cement Red, Grey, or Green Paint	6	4	6	15
LIGHT	White Stone Light Colored Cement White Paint	4	2	4	9

Notes: 1. The F degrees noted are to be added to the normal temperature difference to compensate for sun effect in calculating transmission heat gain.
 2. Not to be used for air conditioning design.
 3. Add 50% to charted values for buildings adjacent to highly reflective surfaces such as sun, water, or heat-repellent glass.

TABLE 4A AVERAGE AIR CHANGES PER 24 HRS FOR MED. TEMPERATURE (ABOVE 32°F) ROOMS DUE TO INFILTRATION AND DOOR OPENINGS

VOLUME CU FT	AIR CHANGES PER 24 HR	VOLUME CU FT	AIR CHANGES PER 24 HR	VOLUME CU FT	AIR CHANGES PER 24 HR	VOLUME CU FT	AIR CHANGES PER 24 HR
200	44.0	1000	17.5	6000	6.5	30000	2.7
300	34.5	1500	14.0	8000	5.5	40000	2.3

TABLE 7 ICE CREAM DATA

PERCENT OF OVERRUN	HARDENING LOAD BTU/GAL ICE CREAM
60	532
70	500
80	470
90	447
100	425
110	405
120	386

Notes:

$$1. \% \text{ overrun} = \frac{(\text{wgt/gal of mix}) - (\text{wgt/gal ice cream})}{\text{wgt/gal of ice cream}}$$

2. Values based on entering temp. of 25°F (30% frozen).

$$3. \text{ Formula: Product Load (Btu/h)} = \frac{\text{no. of gal} \times \text{Btu/gal}}{\text{hardening time (hrs)}}$$

4. 8-10 hr hardening time should be used with forced-air circulation; adjust the calculated load for 18-20 hr compressor operation.

5. See Table 42 for prefigured 24 hr hardening loads at 28°F ent. temp. & 18 hr comp. operation (the values charted in Table 42 must be adjusted for the desired hardening time — i.e., 8 or 10 hrs).

6. At 100% overrun, avg. wgt/gal is 4.6 lb with 60% water content.

7. Estimate hardening rooms at a peak daily production rate of 3.3 gal/sq ft and for a storage capacity of 10 gal/sq ft, if sized to stock all flavors.

8. Estimate storage rooms @ 25 gal/sq ft when stacked solid 6 ft high (including aisles).

TABLE 8 TIME CYCLE FACTORS

APPLICATION	RECOMMENDED FACTORS	
	24 HOUR (DIVIDE BY)	HOURLY (MULTIPLY BY)
Coil Temp. Above 32°F — No Frost Accumulation	24	1.0
Light Frost With Positive Defrost Systems	22	1.1
Med. Temp. With Positive Defrost Systems	20	1.2
Low Temp. With Positive Defrost Systems	18	1.3
Off Cycle Defrost, 35°F or Higher Storage Temp., With Evap. Temp. Below 32°F	16	1.5

Note: Factors noted are for average frosting. For heavier frost, or lower than normal evap. temps., use 1.2 hrs less oper. time.

						35	80-85	—	31	75-80	—	—

Notes: 1. Specific heats for products not listed may be estimated as follows:

Specific heat above freezing = $0.20 + (0.006 \times \% \text{ water})$

Specific heat below freezing = $0.20 + (0.003 \times \% \text{ water})$

2. Latent heats of fusion for products not listed may be estimated as follows:

Heat of fusion = $\% \text{ water} \times 143.4 \text{ Btu/lb}$

3. Average value.

4. Eggs with weak albumen freeze just below 30°F.

5. Lemons in terminal markets are customarily stored @ 50-55°F; sometimes, 32°F is used.

6. Optimum storage temperature varies widely with variety and/or section where grown. Recommended temperatures for apples, as an example, range from 32°F (Golden Delicious) to 38°F (McIntosh). See USDA handbook #66.

7. Permissible storage period varies widely with variety. See USDA handbook #66.

8. Room design conditions critical.

9. Sweet potatoes must be cured for 10 to 14 days @ 85°F & 85-90% rh for successful storage.

10. Relative humidity is left blank (—) in cases where the product is sealed from the air, or the rh % is otherwise non-critical.

11. High humidity required with wood kegs to prevent drying and resulting leaks.

12. Constant humidity desirable.

Ham	105	38	18	1.00	Turnips	70	34	24	1.26
Hogs ^c (carcass)	100	35	18	1.40					

Notes: 1. See Tables 11 & 12 for data on typical beef and pork chilling rooms.

2. Load factor of beets or carrots without tops is 1.

3. Design room temperatures at the completion of the chilling process are generally 2°F below the final product temperature.

4. The following factors apply to any **blast freezing** operation: batch freezing-1.5; continuous process (i.e., conveyor fed) freezing-1.0.

5. Important: Utilization of load factors results in sufficient refrigeration capacity to accommodate the high initial rates of product heat evolution; room temperature rise is thereby minimized. It is to be noted, however, that the application of load factors necessitates a system design compatible with the diverse pulldown & holding requirements. These factors are not to be applied to: (1) small rooms, (2) rooms loaded over an extended period of time, & (3) rooms equipped with single rooftop halocarbon systems.

In cases (1), (2) & (3) above, the chill period should be extended, and the room temperature allowed to rise. (See Page 9 for a more detailed discussion of this subject).

APPENDIX—TABLES

TABLE 11 BEEF CHILLING • • MINIMUM REFRIGERATION REQUIREMENTS IN TONS¹

TOTAL ROOM CAPACITY – HEAD	FLOOR AREA SQ. FT.	18 HOUR CHILL TIME ²		24 HOUR CHILL TIME	
		4 HR LOADING	8 HR LOADING	4 HR LOADING	8 HR LOADING
75	650	23.2	18.2	17.9	15.6
100	800	31.0	24.2	23.8	20.8
250	2000	77.5	60.5	59.5	52.1
450	3600	139.5	109.0	107.2	93.8

Notes: 1. Refrigeration tonnages noted allow for normal room heat gain and defrosting, and are based upon a 65°F temperature pulldown of 550 lb. cattle.

2. An 18 hour chill time requires additional air circulation and lower than normal room temperatures (32-34°F).

TABLE 12 PORK CHILLING • • MINIMUM REFRIGERATION REQUIREMENTS IN TONS¹

TOTAL ROOM CAPACITY – HEAD	FLOOR AREA SQ. FT.	18 HOUR CHILL TIME ²		24 HOUR CHILL TIME	
		4 HR LOADING	8 HR LOADING	4 HR LOADING	8 HR LOADING
75	200	7.9	6.3	6.2	5.5
100	250	10.5	8.4	8.2	7.3
250	625	26.2	20.9	20.6	18.3
450	1125	47.2	37.8	37.0	33.0

Notes: 1. Refrigeration tonnages noted allow for normal room heat gain and defrosting, and are based upon a 65°F temperature pulldown of 200 lb. hogs.

2. An 18 hour chill time requires additional air circulation and lower than normal room temperatures (32-34°F).

TABLE 13 BLAST FREEZING • • PRODUCT LOAD ESTIMATES

PRODUCT	SUPPLY AIR		PRODUCT TEMP., °F		HEAT REMOVED BTU/LB	ESTIMATED TIME OF HEAT REMOVAL HOURS: MINUTES
	TEMP., °F	VELOCITY, FPM	ENTERING	LEAVING		
4 Oz. Hamburger Patties (unwrapped)	-17	400	55	25	119	0:22
2 Oz. Hamburger Patties (unwrapped)	-18	400	40	16	112	0:13
6 Lbs. Ground Beef In Plastic Wrapper (not lean)	-20	1250	39	0	119	9:00
1 Oz. Fresh Pork Sausage (unwrapped)	-13	1000	41	15	101	0:20
12 Oz. - 1 1/4" Thick Strip Steak In Plastic Wrapper	-20	1000	40	0	119	1:03
1 Lb. - 6 Oz. Cooked Chop Suey In Plastic Container	-21	800	64	0	147	2:13
16 Lb. Fresh Turkey In Plastic Wrapper	-24	2600	44	0	130	5:24
12 - 1 Lb.-7 Oz. Containers Of Bar-B-Que Beef In Cardboard Box	-21	1450	78	0	158	10:00

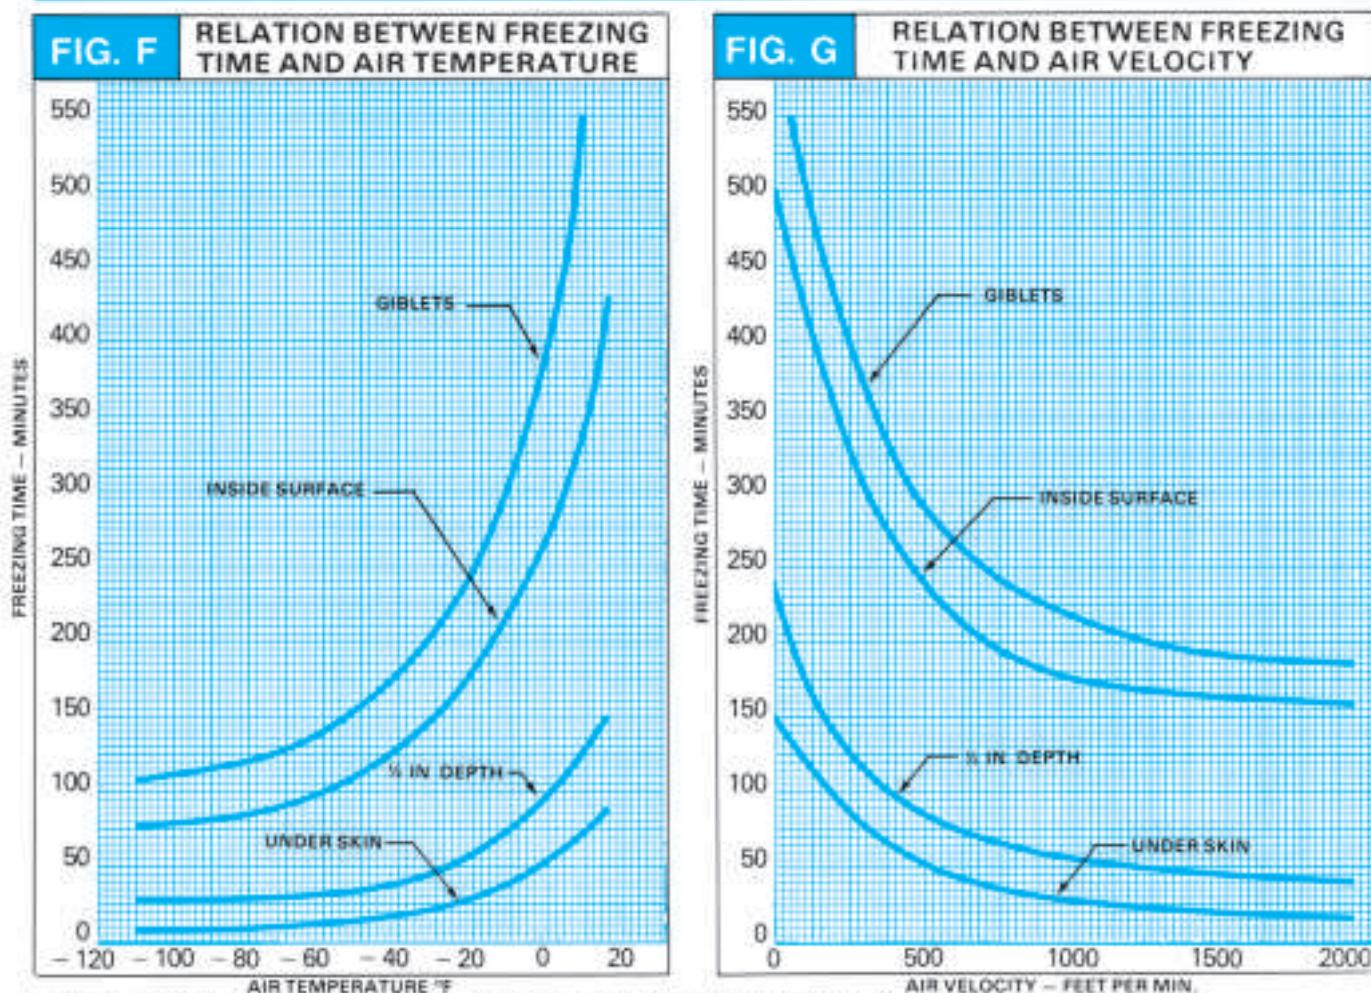

Notes: 1. For a continuous loading operation such as a conveyor or systemized manual feed, the product load in Btu per 24 hrs equals:

$$Q \text{ Btu}/24 \text{ hrs} = \frac{\text{Product per Shift lbs}}{\text{Shift time hrs}} \times 24; \text{ this equation does not apply to "batch loading".}$$

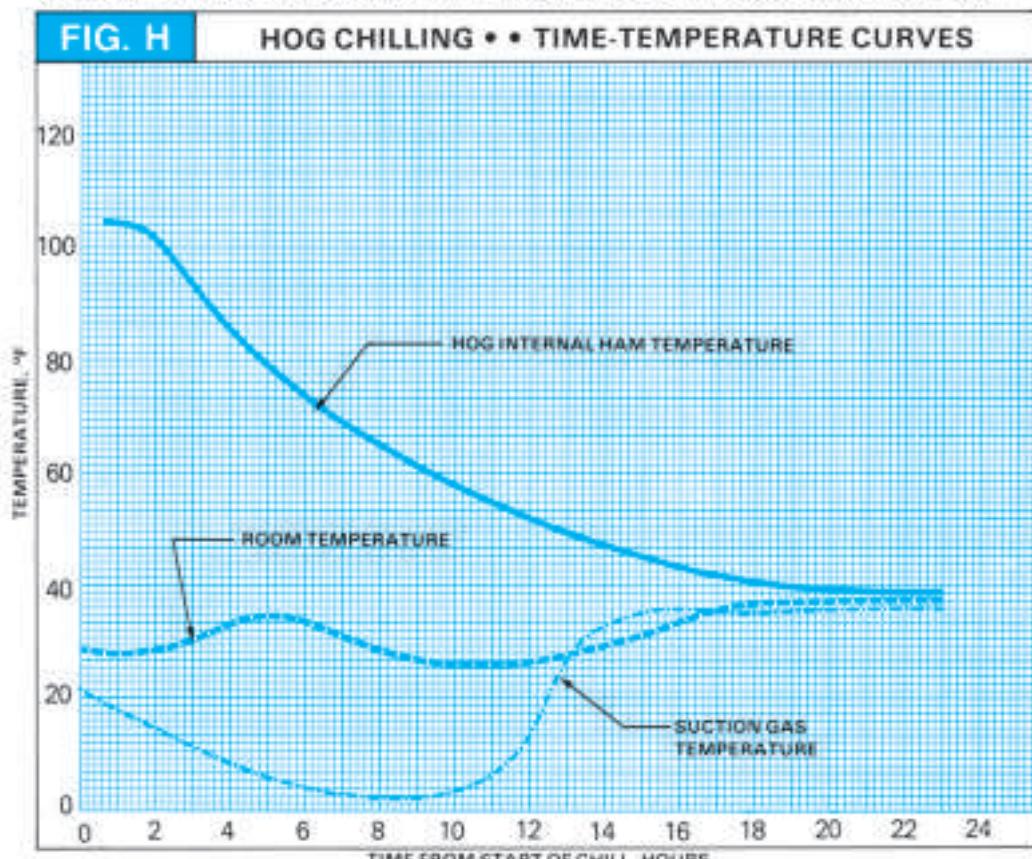

2. The usual transmission, infiltration, lighting, motor and defrosting loads must be added to the product loads listed.

3. In continuous loading operations, the rate of product heat evolution has a negligible effect on the refrigeration load (it does, however, affect room sizing, conveyor size and speed, etc.).

APPENDIX—TABLES

Notes (Fig. F & G):
 1. Freezing time is the time required for product temperature to fall from 32°F to 25°F.
 2. Fig. F based on 5-8 lb. chickens with an initial temperature of 32-35°F, and an air velocity of 450-550 ft./min.
 3. Fig. G based on 5-8 lb. chickens with an initial temperature of 32-35°F, and an air temperature of -20°F

Christmas trees	22-32	80-85	6-7 weeks	—	—

Note: Refer to USDA Handbook No. 66 for additional data relating to flower and nursery stock storage.

APPENDIX—TABLES

TABLE 16
APPLE STORAGE CAPACITY REQUIREMENTS @ 35°F

ENTERING FRUIT ^a TEMPERATURE, °F	MAXIMUM (NOTE 3) RESPIRATION BTU/LB/24 HRS	BTU PER 24 HR PER BOX (NOTES 1, 5 & 8)					
		PERCENTAGE LOADED ON LAST DAY					
		5	10	15	20	25	30
100	9.0	164.6	298.6	432.8	576.9	701.1	835.3
95	7.5	154.0	277.7	401.4	525.1	648.9	772.6
90	6.5	143.5	256.8	370.1	483.4	596.6	709.9
85	5.5	133.1	235.9	338.7	441.6	544.4	647.2
80	4.9	122.6	215.0	307.4	399.8	492.2	584.6
75	4.4	112.2	194.1	276.1	358.0	439.9	445.3
70	3.8	101.7	173.3	244.7	316.2	387.7	459.2
65	3.3	91.4	152.6	213.8	275.0	336.1	397.3
60	2.6	81.0	131.7	182.4	233.2	283.9	334.6
55	2.0	70.5	110.8	151.1	191.4	231.6	271.9
50	1.5	60.1	89.9	119.7	149.6	179.4	209.2
45	1.1	49.6	69.0	88.4	107.8	127.1	146.6
40	0.8	39.2	48.1	57.0	65.0	74.9	83.9

- Notes: 1. The Btu's noted per box represent product load only. The usual transmission, infiltration, and miscellaneous loads must be added.
 2. One box equals one bushel; gross weight = 50 lbs; net weight = 42 lbs.
 3. Respiration heat at 35°F: 0.72 Btu/lb/24 hrs; at 30°F: 0.48 Btu/lb/24 hrs.
 4. Sp. heats: apples: 0.88 Btu/lb/°F; boxes: 0.60 Btu/lb/°F; weighted average: 0.835 Btu/lb/°F.
 5. Loads will be less under C, A, storage conditions.
 6. See Table 10 and Text, Page 9, for applications involving chilling only.
 7. Example: 10000 box storage with ent. temp. of 95°F and last day loading of 15 percent: Product Load = $10000 \times 401.4 = 4,014,000$ Btu/24 hrs.
 8. Apply a 0.95 factor to charted loads if containers are 3.75 lb cardboard cartons in lieu of 8 lb wood boxes.
 9. Hydrocoolers generally pre-cool the fruit to 40°F or 45°F.

TABLE 17
RECOMMENDED COIL TD BY PRODUCT CLASS

COIL TYPE	TEMPERATURE DIFFERENTIAL — °F			
	CLASS 1	CLASS 2	CLASS 3	CLASS 4
FORCED AIR GRAVITY	6 to 9 12 to 16	9 to 12 14 to 18	12-20 16-22	20-25 20-25

- Class 1** Includes products which require very high relative humidities in order to minimize moisture loss during storage. Examples of this category include unpackaged cheese or butter, eggs, and most vegetables if held for comparatively long periods.
- Class 2** Includes products which require reasonably high relative humidities (but not as high as those included in Class 1). Examples of this category include fruits & cut meats in retail storage.
- Class 3** Includes products which require only moderate relative humidities, and includes such products as mushrooms, carcass meats, hides, smoked fish, and fruits such as melons having tough skins.
- Class 4** Includes products which are either unaffected by humidity, or which require specialized storage conditions in which the maximum relative humidity is limited thru use of a reheat system. Examples of the first group are furs, woolens, milk, beer (steel or aluminum kegs), bottled beverages, canned goods & similar products having a protective coating; nuts and chocolates are good examples of the second group.

Note 1: Some supermarket fixtures for cut meat display are designed to operate with lower TD's.

APPENDIX—TABLES

TABLE 18

APPLICATION		TEMP. °F	CEILING HEIGHT, FT	COIL TD. °F	SQ. FT./TON	COMMENTS
DISTRIBUTION CENTER	Storage Cooler	28-40	16-24	Dry Room 9-15 Wet Room 6-9	150-250	Maximum face velocity for light frosted application is 700 fpm; for wet coil operation, face velocity should not exceed 600 fpm; centrifugal or propeller fans are applicable.
	Storage Freezer	-10	16-24	10-15	200-300 7000-10000 cu ft/Ton	Maximum fin spacing of 3-4 fpi; propeller fan units with high face velocities and long air throw are normally used.
			24-40			Low face velocity units (under 650 fpm) are required. Units should blow toward and above the doors to create an air curtain effect. Between-the-rail units are ideal for narrow docks.
MEAT CHILL COOLER	Hogs ²	28-34	16-20	10-12	25-40 10-16 hd/ton	Coil face velocity should not exceed 750 fpm. Between-the-rail units are specifically designed for this application and should be used whenever possible.
	Beef ³				30-45 3-5 hd/ton	
Work Rooms Cutting & Grinding Rooms		35-45	10-12	15-25	125-175	Units with low noise level which distribute air with low velocity or in an umbrella pattern optimize worker comfort.

Notes: 1. Above guidelines are for budgeting purposes only, and should not be used as the sole design criteria.

2. Hog chill rooms average 2-2.5 sq ft per head.

3. Beef chill rooms average 6-8 sq ft per head.

TABLE 19

ROOM SIZE	NO. OF BOXES	WEIGHT, LBS		EVAPORATOR		REFRIGERATION ^{4,5} LOAD-BTU/HR	HEATING LOAD-KW
		GROSS	NET	T.D.	CFM		
1/2 Car	432	20304	18144	15	6000	36,000	4
1 Car	864	40608	36288	15	12000	72,000	8

Notes: 1. Evaporator fan should have $\frac{1}{2}$ " ext. static pressure capability.

2. Weights per box: gross-47 lb; net-42 lb.

3. Specific heats: bananas-0.8 Btu/lb/°F; cartons-0.4 Btu/lb/°F.

4. To calculate load, assume pulldown of 1°F per hour, and peak respiration of 12 Btu/lb/24 hr.

5. Tabulated loads represent total heat removal.

6. Heat is required only to warm a cold load and may not be required.

TABLE 20
U VALUE REVISIONS

EXISTING SECTION PROPERTIES		REVISED U VALUE AT ADDITIONAL RESISTANCE OF						
U	R	4	6	8	12	16	20	24
1.00	1.00	0.20	0.14	0.11	0.08	0.06	0.05	0.04
0.90	1.11	0.20	0.14	0.11	0.08	0.06	0.05	0.04
0.80	1.25	0.19	0.14	0.11	0.08	0.06	0.05	0.04
0.70	1.43	0.19	0.13	0.11	0.07	0.06	0.05	0.04
0.60	1.67	0.19	0.13	0.10	0.07	0.06	0.05	0.04
0.50	2.00	0.18	0.13	0.10	0.07	0.06	0.05	0.04
0.40	2.50	0.16	0.12	0.10	0.07	0.05	0.05	0.04
0.30	3.33	0.14	0.11	0.09	0.07	0.05	0.04	0.04
0.20	5.00	0.11	0.09	0.08	0.06	0.05	0.04	0.03
0.10	10.00	0.06	0.06	0.06	0.05	0.04	0.04	0.03
0.08	12.50	0.06	0.06	0.05	0.04	0.04	0.03	0.03

Example: Given an existing structure with a U value of 0.50, determine the revised U following the addition of insulation having a resistance of 12: enter Column 1 at 0.50 and move horizontally to the column headed by 12; the revised U value may then be read at 0.07.

APPENDIX—TABLES

TABLE 21
FOOD STORAGE ESTIMATING GUIDELINES

PRODUCT CATEGORY		AVERAGE HEAT CONTENT			HIGHEST FREEZING POINT, °F	RECOMMENDED STORAGE CONDITIONS		
		SP HT ABOVE FREEZING	SP HT BELOW FREEZING	LATENT HEAT BTU/LB		TEMPERATURE, °F	RELATIVE HUMIDITY %	
SHORT TERM	LONG TERM							
DAIRY	Butter	.64	.34	15	30	40	—5	80-85
	Cheese, Cream, Eggs, Milk	.85	.40	100	31	35-40	33-35	70-85
	Bananas (Ripe)	.80	.42	108	30.6	56	56	85-90

Notes: 1. Specific heats of beer and carbonated beverages estimated at 1 Btu/lb/°F.

2. Storage areas may be estimated on the basis of 24 cans per one half cubic foot, and 24 bottles per 2 cubic feet; one third additional area should be allowed for aisles.
3. Fiber is utilized for returnable bottle cartons in southern climates.
4. Case weights include partitions, but no bottles or cans.

TABLE 30
INFILTRATION LOADS WHEN STORING BEER CONTAINERS¹

TYPE AND SIZE OF CONTAINER	TEMPERATURE REDUCTION °F IDUTSIDE TEMPERATURE MINUS STORAGE TEMPERATURE					
	80	75	50	45	40	35
Full keg	3200	2800	2100	1700	1400	1100
Half keg	2000	2000	1700	1400	1100	900
Quarter keg	2200	1900	1600	1300	1000	800
Case 24 12 oz. bottles	2100	1800	1500	1200	900	700

Note 1. Loads are in Btu/24 hr. Multiply the number of kegs delivered per day by the appropriate load per keg, and utilize the resultant number as the total 24 hr infiltration heat gain in Part II-B, Form 1E-1.

Kelvin	$\times 1.8 = 459.67 = ^\circ\text{F}$		
°C	$+273.15 = \text{Kelvin}$		
Kelvin	$-273.15 = ^\circ\text{C}$		
Rankine	$+1.8 = \text{Kelvin}$		

Notes:

- No equivalents for the abbreviations "Psia" and "Psig" are utilized in the SI System (if necessary to so designate a given pressure, it would be defined as "an absolute pressure of 50 kpa", or "25 kpa (Gage)", etc.)
- All factors have been rounded off to 4 significant digits and are, therefore, by SI definition "approximate."
- The "E" notation is utilized for convenience in electronic data processing, and has no other significance.
- SI equivalents are always shown as a number greater than 1 and less than 10. Examples: 1.055E + 03 joule per Btu (rather than 1055); 1.000 E - 03 kg per gram (rather than 0.001), etc.

Notes: 1. Ratings based on 3" foamed-in-place urethane, average usage, indoor installation & 18 hour compressor operation.

2. Heights represent internal clearance. Overall heights with floor: 8'6" & 10'6".

3. Correction Factors — Other Ambients: 80°F — 0.75; 100°F — 1.10; 115°F — 1.35

4. Correction Factors — Other Usage: Light (Long-Term Storage) — 0.80; Heavy — 1.15-1.40

5. **IMPORTANT:** Utilization of charted values requires application of properly rated equipment.

		35	—	—	—	150	7659	7916	8172	8428

Notes: 1. Values are for 24 hour pulldown and have been adjusted for 18 hour compressor operation.

2. For shorter pulldown periods, or for continuous blast freezing operations, utilize the following formula:

$$\text{Product Load Btu/hr} = \frac{\text{Charted Value} \times 24}{\text{Pulldown or Shift Time hrs}}$$

3. Ice cream loads must be modified for the preferred hardening period (usually 8-10 hrs) to prevent crystallization.

TABLE 43 GLASS DISPLAY DOOR LOADS IN BTU/HR FOR WALK-IN COOLERS AND FREEZERS

NO. OF DOORS ¹	COOLER@35°F		FREEZER		
	75°F AMBIENT	90°F AMBIENT	80°F TD ²	90°F TD ²	110°F TD ²
2 to 4	960	1200	1800	2100	2600
5 to 7	890	1100	1550	1600	2100
8 to 12	820	1000	1440	1500	2000
13 to 16	630	800	1330	1400	1800
16 to 20	550	700	1240	1300	1600

Notes: 1. Values are per door, and are based on standard 30" x 66" double glazed cooler, and triple glazed freezer doors. Factors for other standard door sizes: 30" x 72": 1.11; 30" x 80": 1.26.

2. Values do not apply to reach-in refrigerators.

3. Unit coolers should be placed opposite and above the doors (blowing toward the doors) to create an air curtain effect.

4. TD represents the difference between box and room temperatures.

Notes:

- Approximate solidification temperature.
- Thermal conductivity units are Btu/(hr)(sq ft)(°F per ft)

APPENDIX—TABLES

TABLE 48
HEAT TRANSFER AND ELECTRICAL FORMULAS

HEAT TRANSFER FORMULAS		KEY TO SYMBOLS
HEAT TRANSMISSION	$Q_{Tot} = U \times A \times \Delta t$	Q_{Tot} — Total Heat in Btu/hr U — Heat Transfer Coefficient in Btu/hr/sq ft/°F A — Surface Area thru which Heat is Conducted Δt — Temperature Difference Between Initial & Final Product Temp., Storage and Outside Temp., or Entering & Leaving Air Temperature
PRODUCT LOADS	$Q_{Tot} = Q_1 + Q_{Lat} + Q_2 + Q_{Res}$ $Q_{Sens} = W \times C_{1,0,2} \times \Delta t$ $Q_{Lat} = W \times h_L$ $Q_{Res} = W \times h_R$	Q_1 — Sensible Product Heat Removal Above Freezing in Btu/hr Q_2 — Sensible Product Heat Removal Below Freezing in Btu/hr Q_{Sens} — Sensible Heat in Btu/hr Q_{Lat} — Latent Heat in Btu/hr Q_{Res} — Respiration Heat in Btu/hr C_1 — Specific Heat Above Freezing in Btu/lb/°F C_2 — Specific Heat Below Freezing in Btu/lb/°F H_L — Latent Heat Of Fusion in Btu/lb H_R — Heat Of Respiration in Btu/hr/lb Cfm — Cubic Feet per Minute ΔH — Enthalpy Difference Between Entering & Leaving Wet Bulb in Btu/lb ΔSH — Specific Humidity Difference (Grains of Water Removed per lb of Air). Gpm — Gallons per Minute T_{EW} — Entering Water Temp. in °F T_{LW} — Leaving Water Temp. in °F W — Product Weight in Pounds
COOLING COILS	$Q_{Tot} = 4.5 \times Cfm \times \Delta h$ $Q_{Sens} = 1.08 \times Cfm \times \Delta t$ $Q_{Lat} = 0.68 \times Cfm \times \Delta SH$ lbs/hr = $\frac{4.5 \times Cfm \times \Delta SH}{7000 \text{ gr/lb}}$	
HEATING COILS	$Q_{Sens} = 1.08 \times Cfm \times \Delta t$	
HEAT RECLAIM AND CONDENSER COILS	$Q_{Sens} = 1.08 \times Cfm \times \Delta t$	
WATER HEATING	$Q_{Tot} = 500 \times Gpm \times (T_{LW} - T_{EW})$	
WATER COOLING	$Q_{Tot} = 500 \times Gpm \times (T_{EW} - T_{LW})$	
ELECTRICAL FORMULAS		CONVERSION FACTORS
Full Load Current = (Single Phase)	$\frac{\text{Watts}}{\text{Voltage}}$	4.5 — Converts Cfm to lbs/hr $4.5 = \frac{60 \text{ Minutes}}{13.35 \text{ ft}^3 \text{ per lb (Spec. Vol.)}}$
Full Load Current = (Three Phase)	$\frac{\text{Watts}}{1.732 \times \text{Voltage}}$	1.08 — Combines 4.5 With Specific Heat $1.08 = 4.5 \times 0.24 \text{ Btu/lb/}^{\circ}\text{F}$
Volts = Amperage × Resistance	$E = I \times R$	0.68 — Combines 4.5 With Heat of Vaporization & Grains per lb $0.68 = \frac{4.5 \times 1054.3 \text{ Btu/lb}}{7000 \text{ gr/lb}}$
Watts = Amperage × Voltage	$P = I \times E$	500 — Converts Gpm Water to lb/hr $500 = \frac{60 \text{ Minutes} \times 62.4 \text{ lb/cu ft}}{7.48 \text{ gal/cu ft}}$
	$P_1 = P_1 \left(\frac{E_2}{E_1} \right)^2$	
Watts (@ Voltage E_2) = Watts (@ Voltage E_1) × $(\text{Volts}_2 / \text{Volts}_1)^2$		

Note: Heat Transfer Formulas are valid for standard air @ 89.6°F. & 14.7 Psig; Conversion Factors must be utilized for other conditions.

Notes: 1. The numbers in bold-face type in the center column refer to the temperature, either in Celsius or Fahrenheit, which is to be converted to the other scale. If converting Fahrenheit to Celsius, the equivalent temperature will be found in the left column; if converting Celsius to Fahrenheit, the equivalent temperature will be found in the column on the right.

2. 1 Degree Celsius = 1 Kelvin

3. Formula: Temp °F = 9/5 Temp °C + 32; Temp °C = 5/9 (Temp °F - 32)

APPENDIX—CHARTS

CHART 1

ESTIMATING UNIT COOLER CAPACITIES

GENERAL:

It is often necessary in the expansion or re-application of a cold storage room to estimate the capacity of existing equipment. Additionally, it is sometimes necessary to physically check evaporators to determine whether they are actually working. Chart 1 may be used for this purpose.

STEPS TO FOLLOW:

(1) Measure entering air temperature (t_i) and leaving air temperature (t_o).

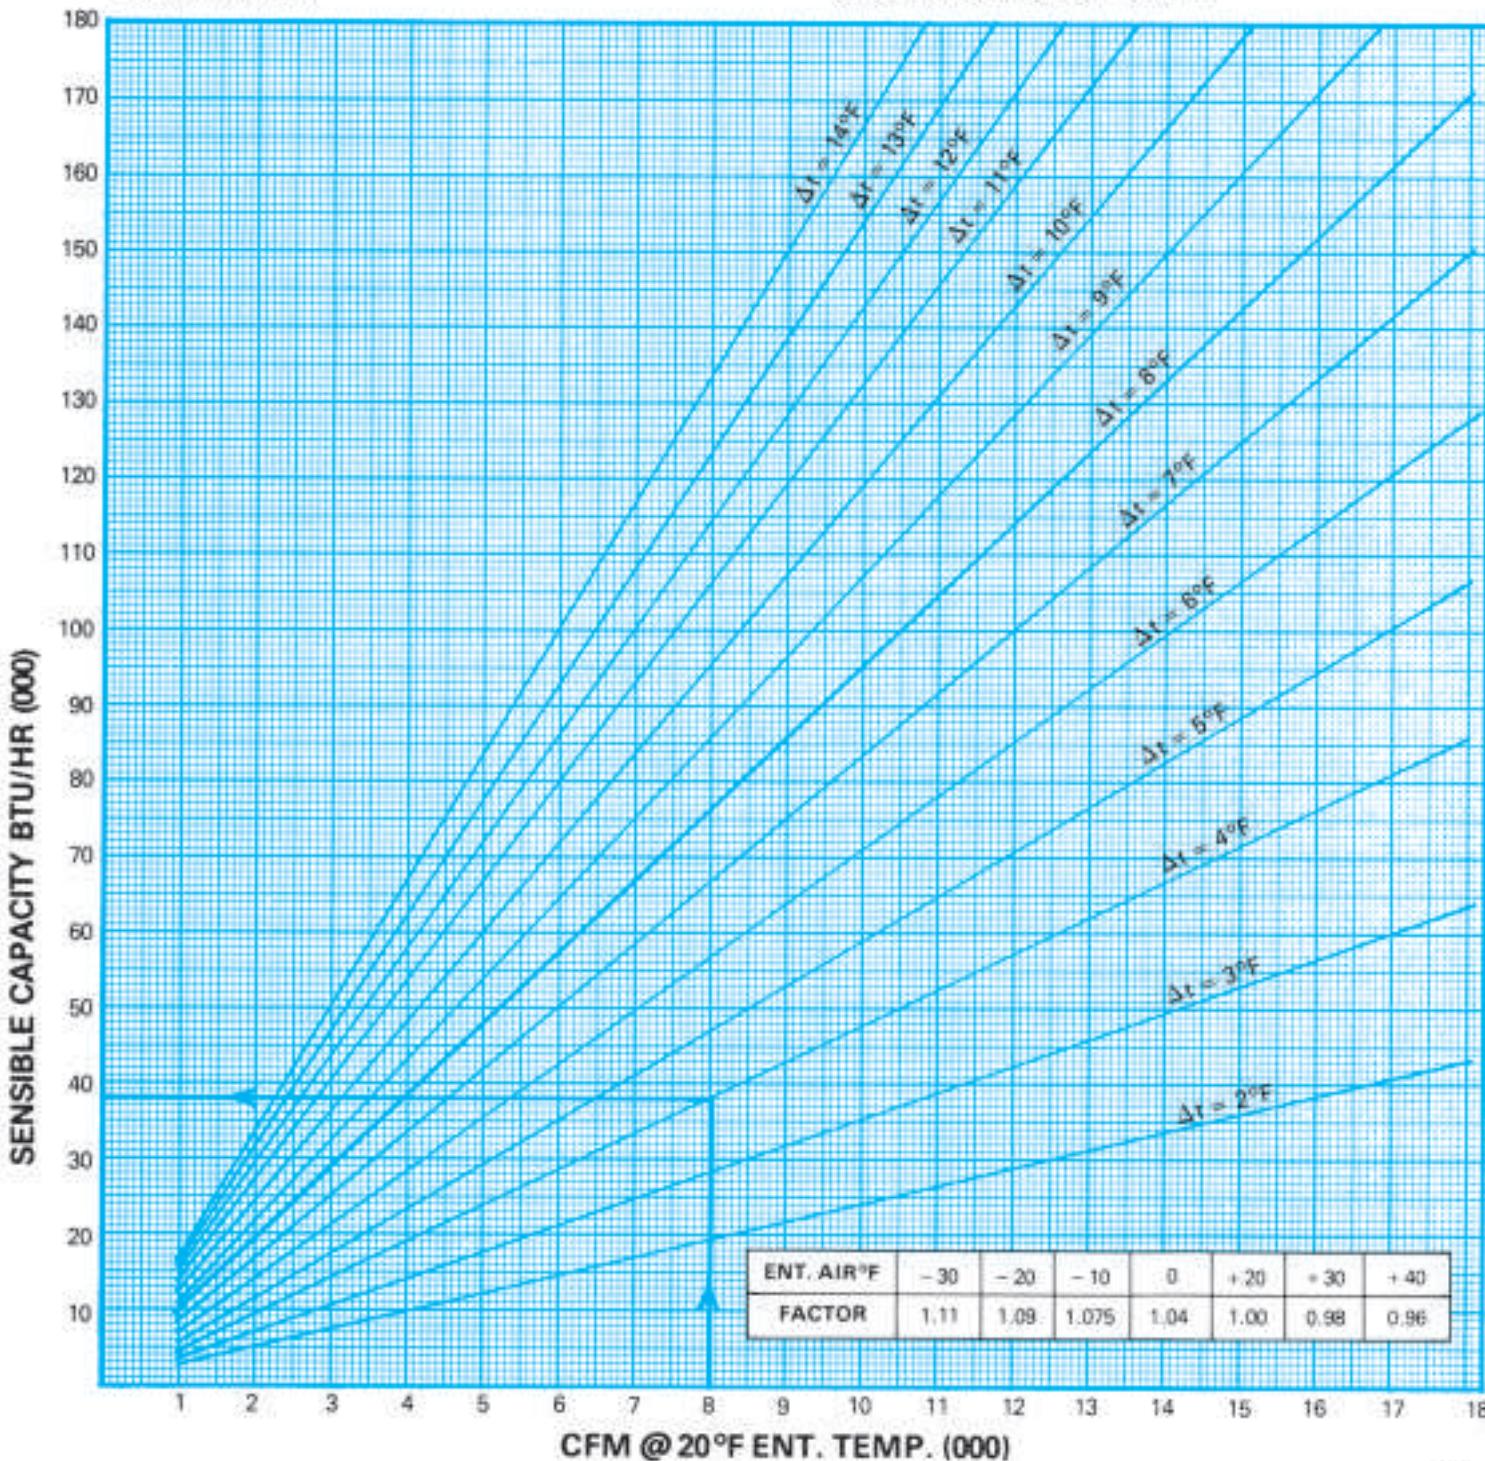

(2) Calculate Δt : $\Delta t = t_{o\text{F}} - t_{i\text{F}}$

(3) Measure face velocity and face area.

(4) Calculate Cfm: $\text{Cfm} = \text{Vel fpm} \times \text{Area ft}^2$

(5) Enter chart on the x-axis at the calculated Cfm and move vertically to the Δt calculated above. Read indicated capacity on the y-axis.

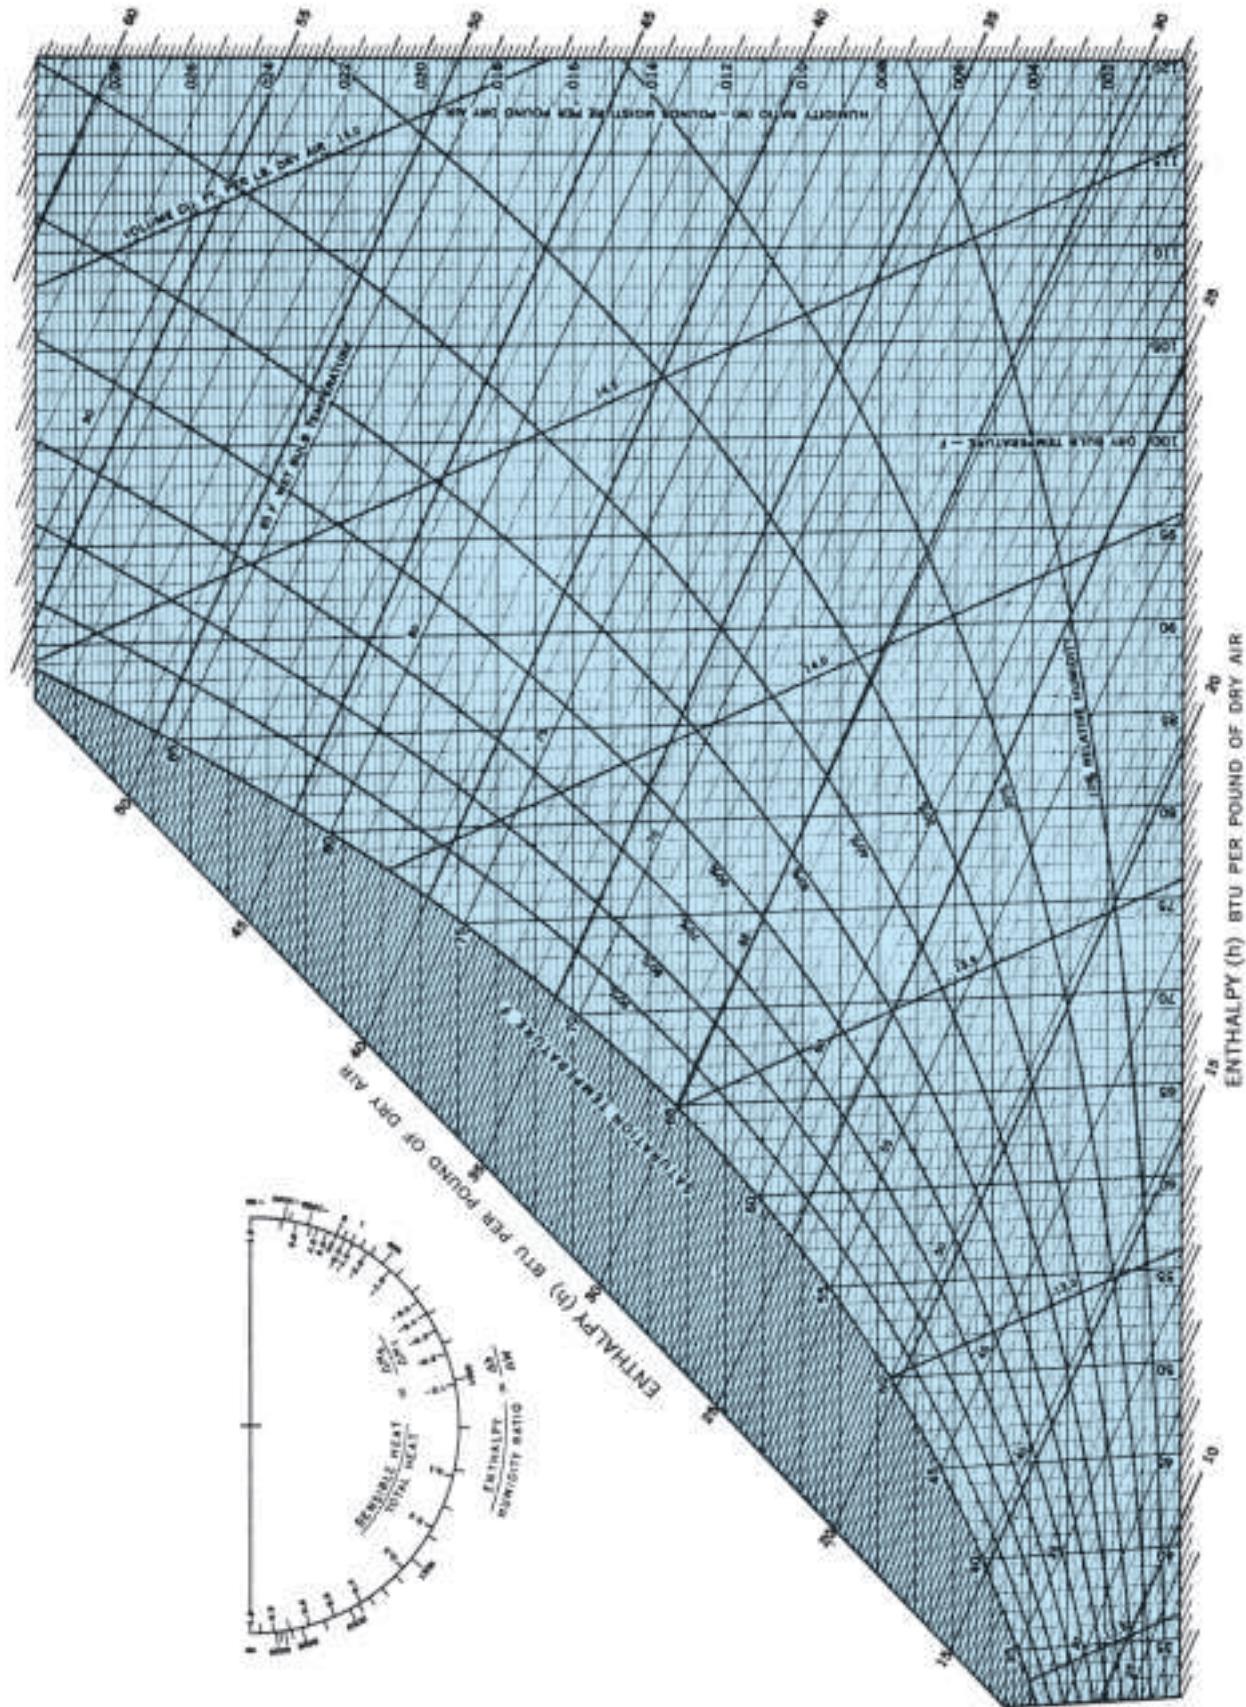

(6) Apply the appropriate correction factor from the chart below to the indicated capacity for entering air temperatures other than +20°F.

INDEX OF APPENDIX

TABLE NO.	DESCRIPTION
1A	Heat Gain Factors for Common Insulating & Building Materials
1B	Heat Transmission Coefficients for Other Insulating & Building Materials
2	Solar Radiation Allowance
3	Motor Equivalencies
4A	Average Air Changes Above 32°F Due to Infiltration & Door Openings
4B	Average Air Changes Below 32°F Due to Infiltration & Door Openings
5	Heat Removed in Cooling Air to Storage Conditions
6	Occupancy Heat
7	Ice Cream Data
8	Time Cycle Factors
9	Properties and Storage Data for Perishable Products
10	Product Chilling Data
11	Beef Chilling — Minimum Refrigeration Requirements in Tons
12	Pork Chilling — Minimum Refrigeration Requirements in Tons
13	Blast Freezing Product Load Estimates
14	Physical Data of Perishable Product Containers
15	Storage Conditions for Cut Flowers and Nursery Stock
16	Apple Storage Capacity Requirements
17	Recommended Coil TD by Product Class
18	Commercial Estimating Guidelines
19	Banana Room Design Parameters
20	U Value Revisions
21	Food Storage Estimating Guidelines
22	Recommended Insulation Thickness
23	Milk Container Data
24	Cheese Make and Cure Data
25	Specific Heats of Milk and Milk Derivatives
26	Other Cheese Cure Data
27	Cheese Freeze Points
28	Cheese Storage Temperatures
29	Beverage Container Data
30	Infiltration Loads When Storing Beer Containers
31	Heat Loads of Keg & Bottled Beer
32	Walk-In Beer Cooler Storage Loads
33	Domestic Outdoor Design Data
34	International Outdoor Design Data
35	SI Metric Conversion Factors
36	Weight Equivalency of Common Measures
37	English-Metric Conversion Factors
38	English Conversion Factors
39	Metric Conversion Factors
40	Outside Area, Room Volume and Refrigeration Load for Walk-In Coolers
41	Average Product Loads for Walk-In Coolers & Freezers
42	Specific Product Loads for Walk-In Coolers & Freezers
43	Glass Display Door Loads for Walk-In Coolers & Freezers
44	Properties of Solids
45	Properties of Water
46	Properties of Air
47	Properties of Liquids
48	Heat Transfer & Electrical Formulas
49	Fahrenheit-Celsius Temperature Conversion Chart
Chart I — Estimating Unit Cooler Capacities	
Chart II — Normal Temp. Psychrometric Chart	
Chart III — Low Temp. Psychrometric Chart
